A Synthetic Example of Run Comparison

Aster Research Demo

October 2026

Abstract

This document is demonstration content. Its run names and measurements are synthetic; they are not claims about a trained model. It shows how a manuscript can remain beside run evidence while an author edits and reviews individual passages.

1 Research question

How should a researcher compare two runs when the observed metric and the evidence behind it can differ? A useful workspace keeps the source manuscript, run records, and agent conversation linked without treating an agent response as an experimental result.

2 Method

We illustrate a baseline and a rank-16 configuration. For a metric sequence $m_1, \ldots, m_n$, the displayed last observation is

$$m_{\text{last}} = m_n. \tag{1}$$

This quantity is not automatically a final evaluation score. A comparison is only meaningful when dataset revision, evaluation split, units, and aggregation match.

3 Illustrative results

Run	Configuration	Evidence status
Baseline	reference	demo only
Rank-16	ablation	demo only

Table 1: Synthetic runs used to demonstrate the writing workflow.

4 Limitations

No statistical claim follows from a single example run. Code provenance and evaluation metadata must be checked before reporting a difference as a result. An author can select this paragraph, ask an agent for a clearer formulation, review the proposed text, and then decide whether to edit the manuscript.
